The Polymerization of Vinyl Monomers in the Crystalline State, Initiated by Gamma Rays

ORIG. PUB. : Chem Průmysl, 9, No 1, 41-45 (1959)

ABSTRACT : The polymerization of solid acrylamide (I) under the action of gamma radiation has been investigated. The formation of mixed crystals of I with the acetamide and amide of butyric acid increases the rate of polymerization. A kinetic analysis of the polymerization of vinyl monomers in the crystalline is given. Rate constants for the polymerization reaction have been determined. Changes in the degree of order in the lattice of the mixed crystals affect the kinetics of the polymerization.

TITLE: Roentgenostructural analysis of recrystallization of brass

PERIODICAL: Referativnyy zhurnal, Metallurgiya, no. 2, 1962, 55, abstract 21354
("Rudy i metale nizeł", 1960, v. 5, no. 6, 246 - 249, Polish;
Russian, English, French and German summaries)

TEXT: The X-ray and metallographic methods, and hardness measurement were used to investigate the effect of the deformation degree (10 - 66%), temperature (650 - 800°C), and holding time (3 sec - 20 min) during annealing, on the recrystallization process of M70 brass. Graphs are plotted showing H_v and grain size as functions of the deformation degree and holding time at recrystallization temperature. The author discusses changes in the radiographs, caused by deformation and annealing of the specimens. In X-ray analyses, the width of interference lines was measured which served to determine stresses of II order; from the number of separate spots the size of recrystallized grains was determined. A comparison of methods for the investigation of recrystallization showed that X-ray

TITLE:

The ultrasonic testing of copper and its alloys

PERIODICAL:

Referativnyy zhurnal, Elektronika i yeye primeneniye, no. 1, 1963, 20, abstract 1V 146 (Rudi i metale nisz-el., v. 7, no. 6, 1962, 208-216 (Pol.; summaries in Rus., Eng., Fr. and Ger.))

TEXT:

The authors give observations on the selection of a method of ultrasonic inspection for nonferrous metals. They describe the results of ultrasonic inspection of copper and copper-alloy cylindrical castings, bars and tubes, carried out using the pulsed echo technique as applied in the Polish-produced D18R defectoscopes. The GNL-1 straight probe (20 mm diameter, resonant frequency 4.5 Mc/s) was used for inspection of castings and bars, and the GST-1/70 inclined probe (angle of introduction of the ultrasonic beam 70°, resonant frequency 3 Mc/s) for tubes. The castings were of copper,

Card 1/4

The ultrasonic testing ...

S/275/63/000/001/034/035
B413/D308

brass, copper-nickel alloy CuNi₅, and also aluminum, silicon-manganese, tin-zinc and tin-phosphorus bronzes; the bars were of the same metals. In the inspection, first of all the characteristics of the probes were determined, in the form of a relation between the base pulse and frequency, and also the detectability of artificial defects, in the form of the relation between the intermediate pulse and the diameter of the defect. The artificial defects were flat-bottomed holes drilled out parallel to the longitudinal axis for castings and bars, and normal to the generators for tubes. The optimum frequencies were 4.5 Mc/s for castings, 1.5 Mc/s for bars and 3 Mc/s for tubes. The determination of probe characteristics and detectability was performed on castings and bars of aluminum bronze possessing a fine-grained structure. Castings with a coarse-grained structure (copper, silicon-manganese and tin-zinc bronzes) under inspection conditions displayed a strong attenuation of the ultrasonic waves, which indicated that inspection of them was not possible by ultrasonic means. In the process of preliminary inspection of specimens with artificial defects, it was proved possible to detect defects with diameters less than 4 mm

Card 2/4

The ultrasonic testing ...

S/275/63/000/001/034/035
D413/D308

in castings, and with diameters of about 2 mm in bars and tubes. After this preliminary inspection, bars and tubes were inspected in which natural defects were present. The production inspection of these articles showed that detection is affected not only by grain size and frequency but also by heterogeneity of the structure. The pulses are reflected from the transition boundary between one structure and another just as from a defect, and this hinders the deciphering of the picture on the CRT screen. Hence analysis of the oscillograms must be carried out with allowance for the structure of the metal and its preparation process. Production testing confirmed that ultrasonic inspection is possible for bars and tubes of copper and all its alloys. Under production conditions the only castings that can be reliably inspected by ultrasonic means are those of aluminum bronze. In order to check their correctness, the results of industrial ultrasonic inspection were compared with the results of metallographic examinations. The authors indicate the value of ultrasonic defectoscopy for inspection of copper and copper-alloy castings between operations.

AUTHORS: Morawiec, H. and Joszt, K.

TITLE: The influence of the structure of copper and its alloys on ultrasonic wave attenuation

PERIODICAL: Referativnyy zhurnal, Avtomatika i radioelektronika, no. 12, 1962, 15-16, abstract 12-5-30 ya (Prace Inst. hutn., v. 14, no. 1, 1962, 55-62 (Pol.))

TEXT: Existing theories of absorption and scattering of elastic waves in crystalline bodies are reviewed. A general expression for the attenuation coefficient is given for the case of Rayleigh and diffusive scatter. The work of Zeeman and Bentz as well as Roth and Krautkremer on the effect of structure inhomogeneity on the attenuation coefficient in metals is mentioned. Experiments are reviewed which help to clarify the influence of grain size and of structure inhomogeneity on the attenuation coefficient of copper and copper alloys. Ultrasonic attenuation had been studied in preliminary experiments on copper, copper-nickel alloy, brass and

Card 1/3

The influence of the ...

8/194/62/000/012/061/101
D295/D308

silicon-manganese, tin-phosphorus and aluminum bronzes. In the first two bronzes, having a large-grain structure, strong ultrasonic absorption was observed, as is evidenced on the oscillograms by the absence of bottom echo and by the presence of multiply-repeated pulses. A pronounced bottom echo was found to be characteristic of finely-grained aluminum bronze. An experimental method is described for determining the attenuation coefficient by proceeding from the pulse-amplitude ratio of two subsequent reflections. The object of these experiments was a more detailed study of the influence, on the attenuation coefficient, of the structure of copper and its alloys in the cast state and after mechanical treatment under pressure. They were carried out at a frequency of 1.5 Mc/s using the DIBR defectoscope of the Polish firm 'Radio-technika'. Copper, brass and aluminum bronze were tested in the cast state. A rapid increase of the attenuation coefficient with grain size was observed in copper and brass (especially in copper with a globular structure). The example of aluminum bronze has served to show the strong influence on the attenuation coefficient not only of grain size but also of grain distribution. The possi-

Card 2/3

8/194/62/000/012/061/101
D295/D308

The influence of the ...

ability of using ultrasonic defectoscopy to test ingots of this bronze has been established. An investigation of ultrasonic absorption in rods made by extrusion from brass ingots, rods of aluminum bronze and tubes of copper-nickel alloy is described. As a result of investigation of ultrasonic absorption in brass rods along their whole length, it was observed that the increase of the attenuation coefficient is caused simultaneously by the increase in grain size and inhomogeneity of grain distribution. In the process of testing bronze rods, bumps were observed on the oscillograms at the places of separation of different structures, similar to echo-signals from defects. These tests have confirmed the possibility of detecting hardened layers by ultrasonic techniques. Tests on tubes carried out at a frequency of 3 Mc/s, using inclined probes, have served to interpret oscillograms when inhomogeneities exist in the metal. 9 figures. 10 references. AUTHORS: Morawiecki, Andrzej, Siemion, Ignacy Z., Nowak, Kornel

TITLE: Possible tautomerism in carbobenzoxy groups of carbobenzoxyamino acids

PERIODICAL: Referativnyy zhurnal. Khimiya, no. 2, 1963, 167-168, abstract 2Zh4 (Roczn. chem., v. 36, no. 5, 1962, 983-986 [Eng. summary in Pol.])

TEXT: Solutions of N-carboboxy derivatives of L-alanine (I), L-proline (II), L-tryptophan (III) and L-phenylalanine (IV) were studied by spectropolarimetry. The rotatory dispersion curves of I in methanol and benzene solutions are close, and in the case of II they practically coincide, being located in the region of negative $[\alpha]_D$ values. The rotatory dispersions (RD) of III and IV are represented by curves which differ substantially as a function of the polarity of the solvent; the RD curve of III in dioxane and that of IV in C_6H_6 lies within the region of positive $[\alpha]_D$ values, whereas the RD curve of III in CH_3OH is in the

Card 1/2

Possible tautomerism in ...

B/081/63/000/002/024/088.
B166/B138

negative region. IV in a methanol solution changes the positive sign of its rotation to negative as $\lambda(\text{max})$ increases. The results obtained lead to the assumption that the reason for the changes in the RD of derivatives of aromatic amino acids, III and IV, is enolisation of the carbonyl in the N-carbobenzoxy group: $\text{C}_6\text{H}_5\text{CH}_2\text{OC(O)NHR} \rightleftharpoons \text{C}_6\text{H}_5\text{CH}_2\text{OC(OH)=NR}$.

No similar phenomenon is observed in the case of aliphatic N-carbobenzoxy amino acids. [Abstracter's note: Complete translation.]

TOPIC TAGS: cell physiology, dipole moment, electron charge, water

ABSTRACT: The subject is considered on the basis of recent theories that water in living cells is something more than a mere solvent; it is also a biochemically active substance whose state and structure in the cells may in many cases regulate the vital processes. The crystalline structure of water is considered for the solid(ice), liquid and gaseous states of this substance in relation to the dipole moment and positive and negative charges of the hydrogen and oxygen atoms, and their effect on the vital functions of the organism is discussed. TITLE : Results of Investigations of Blastings at
Sialite near Mitya Potok in the Donetsk
District

ORIG. PUB. : Kvant. geol., 1957, 2, No 3-4, 261-265, 266

ABSTRACT : The investigations covered the following: geologic occurrence, economic conditions (mining, petrographic and chemical composition, complete analyses of rocks and silicate inclusions), technological characteristics (strength, water permeability, porosity, frost resistance, etc.). The blaststones are recommended as a better material and as raw material for the production of quicklime and metallurgical flux. -- G. Veron'yev.

Title : Note on the Silicified Sandstones from Swieci
(Konin District)
Orig Pub. : Arch Mineral, 21, No 1, 101-110 (1956) (1957)
Abstract : The authors describe local formations of silicified sandstones and loamy rocks of varying particle size distribution. The suggestion is advanced that these rocks constitute lake deposits of the Miocene period. The sandstones consist of terrigenous quartz grains, cemented with chalcedony and opal. According to the results obtained from incomplete silicate chemical analyses, microscopic examinations, determinations of the mechanical composition and of technical properties have shown that a number of varieties can be used as raw materials in the production of industrial refractories.

"On the Retroretinal Component of Optical Recognition."

Warsaw, Polski Tygodnik Lekarski, Vol 18, No 19-20, 6-13 May 63, pp 667-670.

Abstract: [Author's English summary] Experiments have proven three stages of optical recognition: 1) Elementary observation, 2) relative recognition, and 3) absolute recognition. The effect of the retroretinal component on the recognition or vision is 35--130 percent. The Auber-Forster phenomenon is due to the relative recognition, and if the effect of the retroretinal component, the phenomenon disappears. The literature confirming these observations is cited in the body of the text.

AUTHOR: Morawska, Maria

TITLE: Changes in the cloudiness and insolation at Cracow

PERIODICAL: Referativnyy zhurnal, Geofizika, no. 12, 1962, 55,
abstract 123562 (Iszechświat, no. 6, 1962, 21-144
(Pol.))

TEXT: The author discusses the results of an analysis carried out at the astronomical observatory of the Jagielloński university (~~Jagielloński~~ University) in Cracow, on the cloudiness data for 1859-1958 and those of the sunshine over 1884-1958. The analysis was performed by the method of moving 10-year averages. The tendency for the general cloudiness to increase after its minimum in 1905 is traced. Latter decades are characterized by high cloudiness. In 100 years the number of clear days decreased almost by a factor of two. The number of overcast days has two clearly expressed maxima (in the seventies of the last century and in the forties of this century) and one distinct minimum (in the nineties). ✓

Card 1/2

Changes in the cloudiness ...

S/169/62/000/012/059/095
D228/0307

The curve for the number of semiclear and semiovercast days is a reflection of the number of overcast days. A distinct reduction in the number of hours of sunshine is noted, this being observed with little change throughout the period under consideration. At the present time the duration of sunshine reaches scarcely 37% of the maximum possible period. Changes in the cloudiness and the circulation of sunshine are correlated with variations in the period under review. The tendencies in latter decades are however clearly due to the influence of local causes, chiefly to the increased pollution of the atmosphere at Cracow by aerosols brought from the Upper Silesian mining-industrial district by westerly winds with a frequency of up to 40%. South-westerly winds with a frequency of 30% bring aerosols from the industrial areas of Skawina, and easterly winds bring them from the nearby combine of Nowa Huta. On meeting stagnant conditions, the industrial impurities due to the basinlike location of Cracow become sources of condensation nuclei and cause cloudiness to increase and the number of hours of sunshine to decrease.

TITLE: Fog observations at Cracow (1861-1960)

SOURCE: Przegląd geofizyczny, no. 3, 1966, 171-181

TOPIC TAGS: ^{aeronaucic} ~~aviation~~ meteorology, fog, ~~airport fog~~, ~~win~~ fog, air pollution

ABSTRACT: The city of Cracow has a high incidence of days with fog. The 100-year average is 60 days per year with fog, and this figure has increased to 78 days in the past decade. This large increase is probably connected with the considerable progress in industrialization during that period. The 100-year period included 14 years in which the number of days with fogs exceeded 100; two such years occurred near the end of the period. During 1958-1960, there was an annual difference of 78 foggy days between the center of the city and its outlying areas. A comparison of the curve of the number of days with fog and the curve of dif-

Card 1/3

ACC NR: AP7000287

ferences in summer and winter temperatures indicates quite good agreement. This implies that under these conditions, greater continental influence may contribute to a numerical increase in the number of days with fog and greater oceanic influence to a decrease in their number (see Figs. 1 and 2).
